Sorting Algorithms

CSC 3130-02

02/03/2026

1. Merge Sort:

Adding the smallest element among the two arrays to a new array

Step 1: $\text{list1}[0] = 1$ and $\text{list2}[0] = -3$, $-3 < 1$, $\text{outList} = [-3] \rightarrow \text{list1} = [1, 2, 3, 6]$,
 $\text{list2} = [0, 6, 7]$

Step 2: $\text{list1}[0] = 1$ and $\text{list2}[1] = 0$, $0 < 1$, $\text{outList} = [-3, 0] \rightarrow \text{list1} = [1, 2, 3, 6]$,
 $\text{list2} = [6, 7]$

Step 3: $\text{list1}[0] = 1$ and $\text{list2}[2] = 6$, $1 < 6$, $\text{outList} = [-3, 0, 1] \rightarrow \text{list1} = [2, 3, 6]$,
 $\text{list2} = [6, 7]$

Step 4: $\text{list1}[1] = 2$ and $\text{list2}[2] = 6$, $2 < 6$, $\text{outList} = [-3, 0, 1, 2] \rightarrow \text{list1} = [3, 6]$,
 $\text{list2} = [6, 7]$

Step 5: $\text{list1}[2] = 3$ and $\text{list2}[2] = 6$, $3 < 6$, $\text{outList} = [-3, 0, 1, 2, 3] \rightarrow \text{list1} = [6]$,
 $\text{list2} = [6, 7]$

Step 6: $\text{list1}[3] = 6$ and $\text{list2}[2] = 6$, $6 == 6$, $\text{outList} = [-3, 0, 1, 2, 3, 6] \rightarrow \text{list1} =$
empty, $\text{list2} = [6, 7]$

Step 7: since list1 is empty, add rest of $\text{list2} \rightarrow \text{outList} = [-3, 0, 1, 2, 3, 6, 6, 7]$

2. Insertion Sort:

Insert key into the sorted part

List = $[-21, 5, 7, -10, 61, 8, 3, 10]$

Step 1: ($i = 1$, $key = 5$) $sorted = [-21]$, insert 5 into $[-21]$, 5 is already ≥ -21 so no shift $\rightarrow [-21, 5]$

Step 2: ($i = 2$, $key = 7$) $[-21, 5]$, insert 7 into $[-21, 5]$, $7 \geq 5$ so no shift $\rightarrow [-21, 5, 7]$

Step 3: ($i = 3$, $key = -10$) insert -10 into $[-21, 5, 7]$, $7 > -10$ so shift, $5 > -10$ so shift, $-21 < -10$ so stop $\rightarrow [-21, -10, 5, 7]$

Step 4: ($i = 4$, $key = 61$) insert 61 into $[-21, -10, 5, 7]$, $61 > 7$ so no shift $\rightarrow [-21, -10, 5, 7, 61]$

Step 5: ($i = 5$, $key = 8$) insert 8 into $[-21, -10, 5, 7, 61]$, $61 > 8$ so shift, $7 < 8$ so stop $\rightarrow [-21, -10, 5, 7, 8, 61]$

Step 6: ($i = 6$, $key = 3$) insert 3 into $[-21, -10, 5, 7, 8, 61]$, $61 > 3$ so shift, $8 > 3$ so shift, $7 > 3$ so shift, $5 > 3$ so shift, $-10 < 3$ so stop $\rightarrow [-21, -10, 3, 5, 7, 8, 61]$

Step 7: ($i = 7$, $key = 10$) insert 10 into $[-21, -10, 3, 5, 7, 8, 61]$, $61 > 10$ so shift, $8 < 10$ so stop $\rightarrow [-21, -10, 3, 5, 7, 8, 10, 61]$

3. Quick sort:

Repeatedly partitions input into low and high parts then recursively sorts each part

Array = $[-5, 4, 2, 619, 11, 5, 620, -3]$

Step 1: $pivot = 619$, $low (\leq 619)$: $[-5, 4, 2, -3, 11, 5]$, $high (\geq 619)$: $[620, 619] \rightarrow quicksort([-5, 4, 2, -3, 11, 5])$ and $quicksort([620, 619])$

Step 2: $quicksort([-5, 4, 2, -3, 11, 5])$, $pivot = 2$, $low (\leq 2)$: $[-5, -3, 2]$, $high (\geq 2)$: $[4, 11, 5] \rightarrow quicksort([-5, -3, 2])$ and $quicksort([4, 11, 5])$

Step 3: $quicksort([-5, -3, 2])$, $pivot = -3$, $low (\leq -3)$: $[-5, -3]$, $high (\geq -3)$: $[2] \rightarrow result: [-5, -3, 2]$

Step 4: quicksort([4, 11, 5], pivot = 11, low(\leq 11): [4, 5], high(\geq 11): [11] \rightarrow
result: [4, 5, 11]

Step 5: combine results of step 3 and 4: [-5, -3, 2, 4, 5, 11]

Step 6: quicksort([620, 619]), pivot = 620, low(\leq 620): [619], high(\geq 620):
[620] \rightarrow result: [619, 620]

Final sorted list: [-5, -3, 2, 4, 5, 11, 619, 620]

4. Shell sort:

Treat the list as interleaved arrays determined by gap value K, sort each
interleaved array using insertion sort style shifting, then finish with normal
insertion sort

Array = [5, 10, 60, 0, -1, 34, 6, 10]

Gap K = 4

Step 1: Compare indices (0,4): [5, -1], $-1 < 5$ so shift, insert -1 \rightarrow [-1, 10,
60, 0, 5, 34, 6, 10]

Step 2: Compare indices (1, 5): [10, 34], already in order, no shift \rightarrow [-1,
10, 60, 0, 5, 34, 6, 10]

Step 3: Compare indices (2, 6): [60, 6], $6 < 60$ so shift, insert 6 \rightarrow [-1, 10,
6, 0, 5, 34, 60, 10]

Step 4: Compare indices (3, 7): [0, 10], already in order, no shift \rightarrow [-1,
10, 6, 0, 5, 34, 60, 10]

Gap K = 2

Step 5: Sort indices (0, 2, 4, 6): [-1, 6, 5, 60], $5 < 6$ so shift, place 5 after -
1 \rightarrow [-1, 10, 5, 0, 6, 34, 60, 10]

Step 6: Sort indices (1, 3, 5, 7): [10, 0, 34, 10], $0 < 10$ so shift, place 0 before 10 \rightarrow [-1, 0, 5, 10, 6, 34, 60, 10]; $10 < 34$ so shift, place 10 before 34 \rightarrow [-1, 0, 5, 10, 6, 10, 60, 34]

Gap $K = 1$

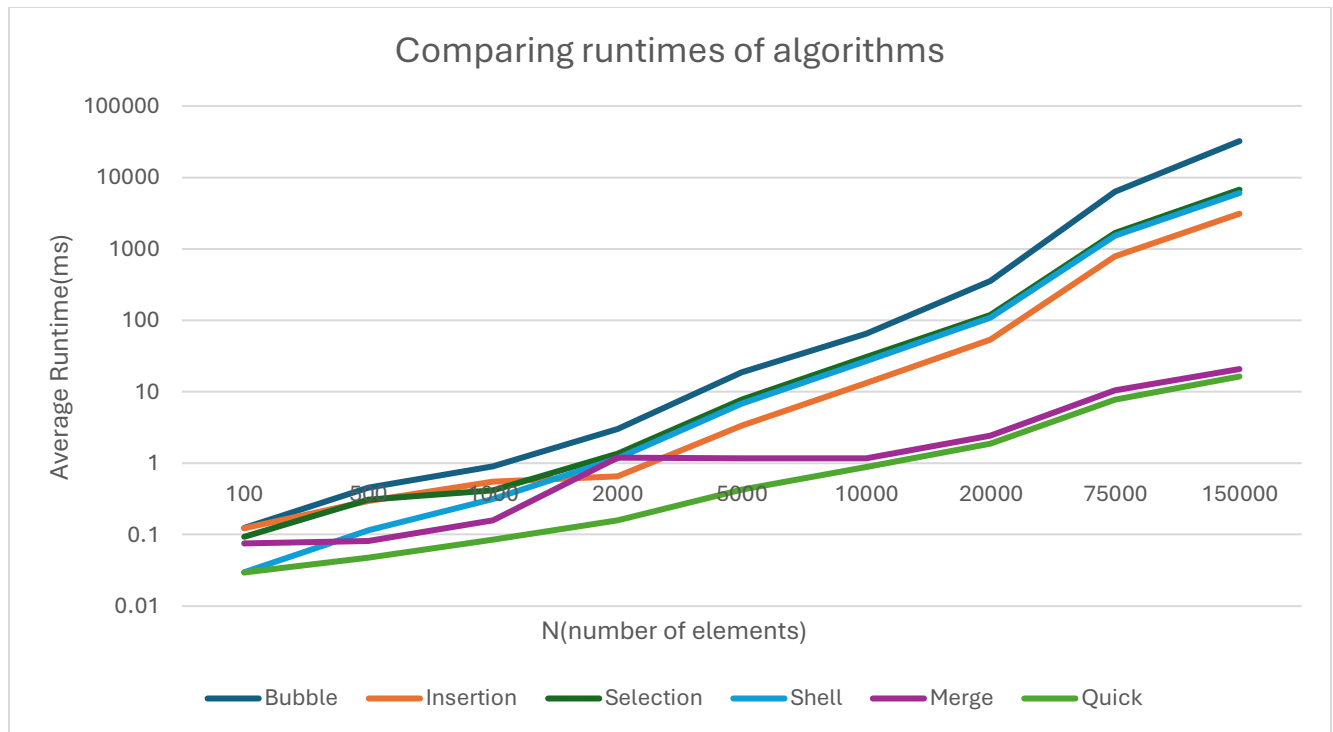

Step 7: Insert 6 into [-1, 0, 5, 10], $6 < 10$ so shift, place 6 after 5 \rightarrow [-1, 0, 5, 6, 10, 10, 60, 34]

Step 8: Insert 34 into [-1, 0, 5, 6, 10, 10, 60], $34 < 60$ so shift, place 34 before 60 \rightarrow [-1, 0, 5, 6, 10, 10, 34, 60]

Final sorted list: [-1, 0, 5, 6, 10, 10, 34, 60]

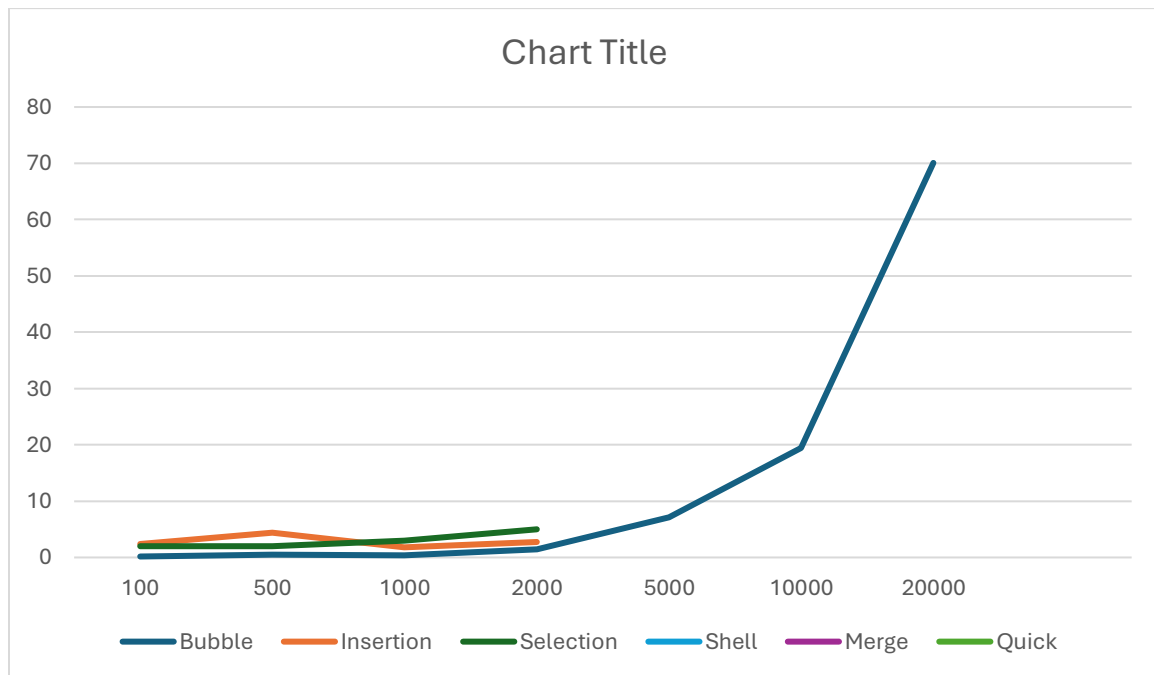

5. Ranking the six sorting algorithms based on asymptotic runtime, from fastest to slowest would be quick sort, merge sort, shell sort, insertion sort, selection sort, and bubble sort. Quick sort and merge sort are tied for the fastest because they run in $(N \log N)$ time. Shell sort is medium run time because the runtime is $(N^{1.5})$. Bubble sort, insertion sort, and selection sort are also tied for the slowest because the runtime is (N^2) .

9.

10. I noticed that the difference in performance times of each sorting algorithm is seen the most clearly as input size increased. Relatively, bubble sort was the slowest while shell sort and selection sort were mostly tied for performance. Furthermore, insertion sort was relatively in the middle in terms of performance time but quick sort and merge sort were relatively the fastest. The actual performance time of quick sort and merge sort matched my predictions based on asymptotic analysis because of their time complexity which is $(N \log N)$ and that they were relatively the fastest. However, my prediction that shell sort would be in the middle was proven incorrectly because the actual performance time shows that insertion sort was relatively in the middle. Finally, based on actual performance time, bubble sort was the slowest while shell sort and selection sort were tied for performance time. The most significant thing I notice though, is that the performance time takes a pivot around 2000 elements because in one instance, insertion sort significantly slows down after 2000 elements. Another instance of this is shell sort which begins much faster than selection sort but then slows down to the relatively same runtime at 2000

elements. I also ran into the issue of large numbers and to try to deal with it, Excel/Word has an option to format the axis with logarithmic scale which I selected and it helped me view the large numbers better.

12.
